

# Thesis Preliminary Exam

Clayton Bennett

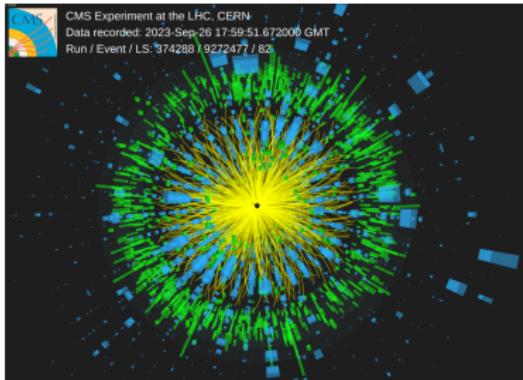

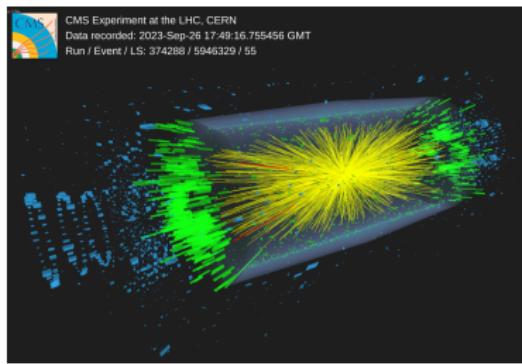

University of Illinois at Chicago  
The CMS Collaboration

December 4, 2023

# Outline

- ① The Quark Gluon Plasma
- ② Jets as probes of the Quark Gluon Plasma
- ③  $b$ -jet measurements with CMS

First 2023 PbPb collision at 5.36 TeV

# **The Quark Gluon Plasma**

# The Standard Model of Particle Physics

QUARKS	mass → ≈2.3 MeV/c <sup>2</sup>	charge → 2/3	spin → 1/2	u	c	t	g	Higgs boson

- Quantum field theory that describes
  - Quantum electrodynamics
  - Electroweak interactions
  - Quantum chromodynamics
  - Gravity
- Quarks and leptons interact via the exchange of gauge bosons
  - QED → γ
  - EW →  $W^\pm, Z$
  - QCD → g
- H is a mass-giving scalar boson
- Experimentally verified

# Quantum Chromodynamics

- **Quantum chromodynamics (QCD)** is a quantum field theory describing the **strong interaction** between **quarks** and **gluons**
- **Confinement:** fundamental feature of QCD
  - Strong force grows with separationS
  - $q\bar{q} \rightarrow q\bar{q} + q\bar{q}$  (particles from vacuum)
- QCD is a quantum field theory with **asymptotic freedom**

$$\alpha_s(Q^2) = \frac{\alpha_s(\mu^2)}{1 + \left[ \alpha_s(\mu^2) \frac{(33 - 2n_f)}{12\pi} \right] \ln \left( \frac{Q^2}{\mu^2} \right)}$$

$$\lim_{Q \rightarrow \infty} \alpha_s(Q^2) \rightarrow 0$$

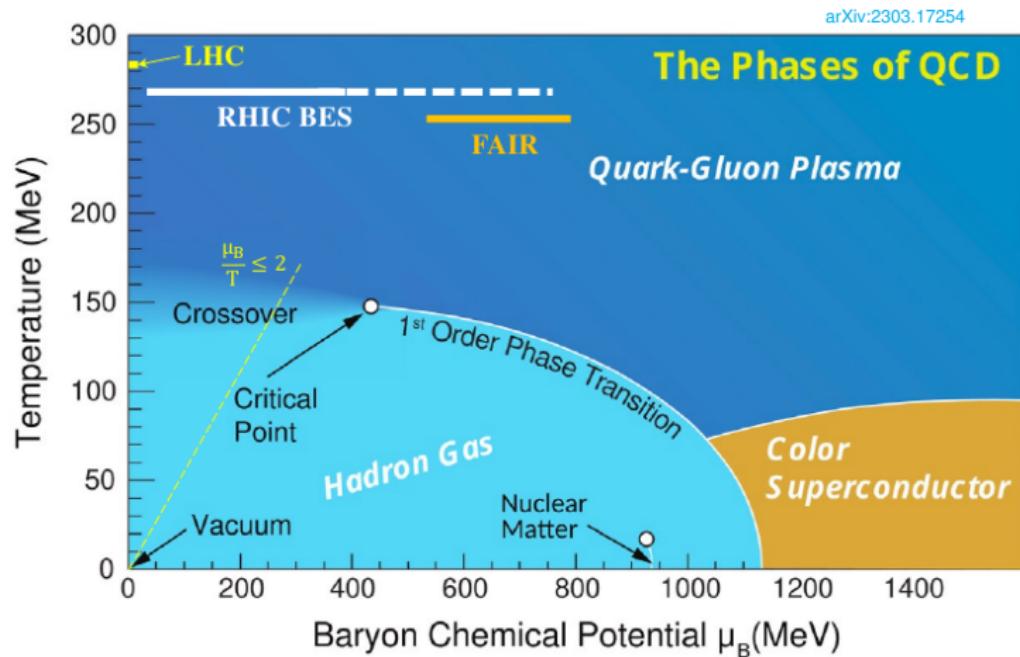

# Deconfinement

- Lattice QCD predicts a deconfined phase of quarks and gluons known as the **Quark Gluon Plasma** at extreme temperatures and pressures
- At  $\mu_B \sim 0$ , the critical temperature for this phase-change is  
 $T_c \approx 158.0 \pm 0.6 \text{ MeV} \approx 1.8 \cdot 10^{12} \text{ K}$

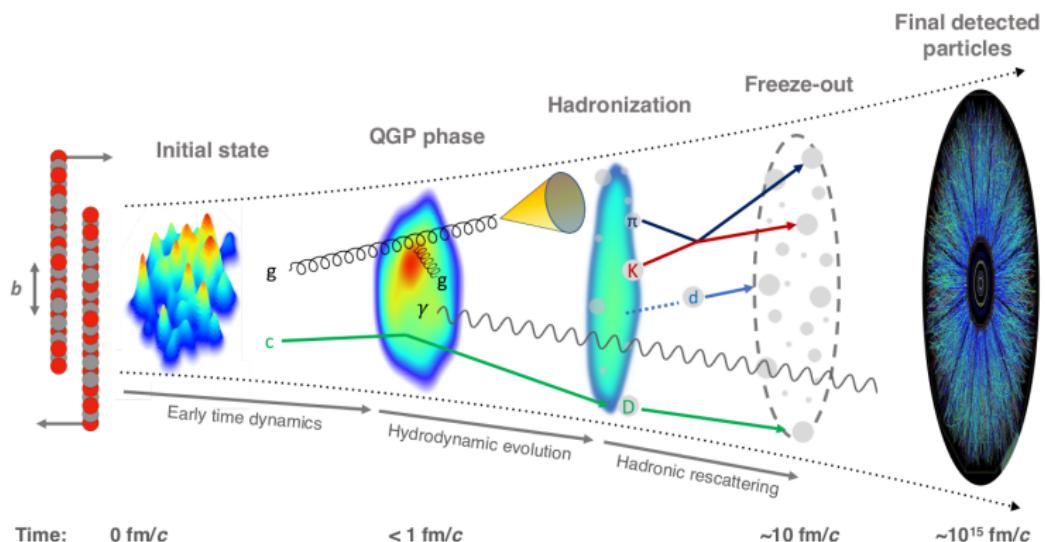

# Phases of QCD

- For  $\frac{\mu_B}{T} \leq 2$ , QGP-to-hadron phase transition is a **smooth crossover**
- Above some critical point, the QGP-to-hadron transition is expected to become a **first-order phase transition**

# QGP at Particle Colliders

- We can create QGP in the lab by colliding heavy nuclei ( $v \approx c$ ) in particle accelerators (such as RHIC and LHC)
- QCD predicts rich phase dynamics prior to particle detection
  - **Strongly-interacting QGP phase** that flows as a relativistic hydrodynamic fluid
  - Medium expansion, cooling, and **hadronization**
  - Hadronic rescattering and **freeze-out**

# Kinematics and Centrality

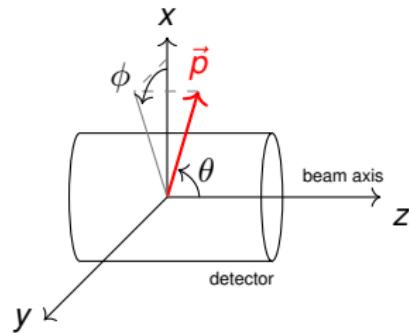

- Detector geometry warrants the use of cylindrical coordinate system

transverse momentum :  $p_T = |\vec{p}| \sin \theta$

$$\text{rapidity} : y = \frac{1}{2} \ln \left( \frac{E + p_z}{E - p_z} \right)$$

$$\text{pseudo-rapidity} : \eta = \frac{1}{2} \ln \left( \frac{p + p_z}{p - p_z} \right)$$

$$\rightarrow -\ln \left[ \tan \left( \frac{\theta}{2} \right) \right]$$

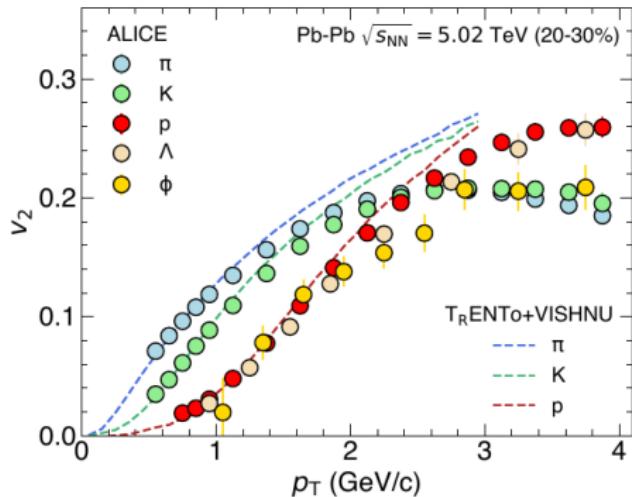

- Why are these variables common in particle physics experiments?
  - $\sum_i p_{T,i} = 0 + \epsilon$
  - $y$  is invariant for boosts along  $z$ -axis

# Flow in the QGP

- QGP is a hydrodynamic fluid → initial spacial anisotropies result in momentum-space anisotropies
- $v_n$  measurements quantify the  $\phi$ -space anisotropy

$$\frac{dN}{d\phi} = A \cdot \left( 1 + 2 \sum_{n=1}^{\infty} v_n \cos [n(\phi - \Psi_n)] \right)$$

- Flow harmonics  $v_n$  are observed to scale with parton number → further evidence of deconfinement

## **Jets as Probes of the QGP**

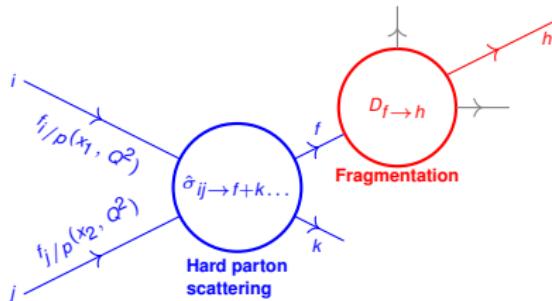

# Factorization Theorems in QCD

- Hard processes in  $p\bar{p}$  → short-distance physics of partons  $\otimes$  long-distance physics of hadrons

Cross-section factorization in  $p\bar{p}$  collisions

$$\begin{aligned} d\sigma^{p+p \rightarrow h+X} &= \sum_f d\sigma^{p+p \rightarrow f+X} \otimes D_{f \rightarrow h}(z, \mu_F^2) \\ &= \sum_{i,j,k,\dots} f_{i/p}(x_1, Q^2) \otimes f_{j/p}(x_2, Q^2) \otimes \hat{\sigma}_{ij \rightarrow f+k\dots} \otimes D_{f \rightarrow h}(z, \mu_F^2) \end{aligned}$$

- We use hard processes in  $p\bar{p}$  collisions as a reference when we study QGP medium effects

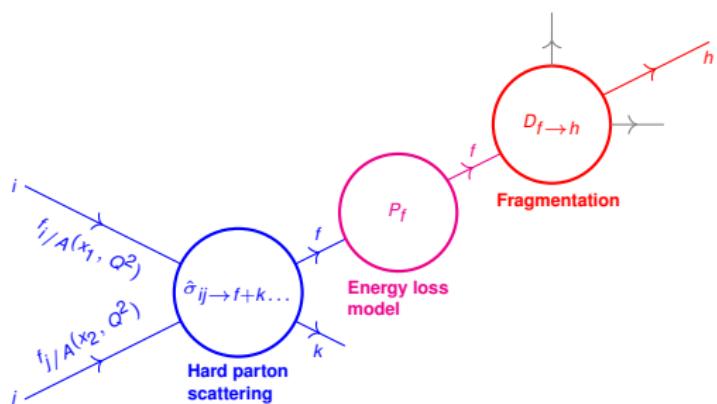

- Cross-section in vacuum is perturbatively calculable!
- Fragmentation is non-perturbative → must rely on QCD-inspired models

# Factorization Theorems in QCD

- Hard processes in AA → short-distance physics of partons  $\otimes$  Model-dependent energy loss of partons in the QGP  $\otimes$  long-distance physics of hadrons

Cross-section factorization in AA collisions

$$d\sigma^{A+A \rightarrow h+X} = \sum_f d\sigma_{(\text{vac})}^{A+A \rightarrow f+X} \otimes P_f(\Delta E, L, \hat{q}) \otimes D_{f \rightarrow h}^{(\text{vac})}(z, \mu_F^2)$$

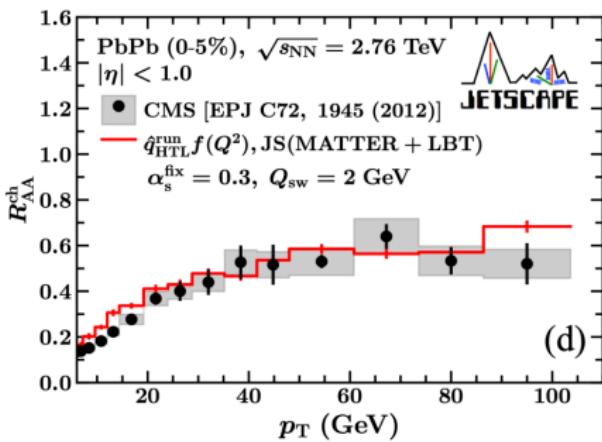

- Factorization theorems unknown for processes embedded in a QGP medium
- Energy loss mechanisms
  - Collisional energy loss
    - ▶ Elastic scattering with medium
    - ▶ Dominant for heavy quarks
  - Radiative energy loss
    - ▶ Inelastic scattering with medium (gluon Bremsstrahlung)
    - ▶ Dominant for light quarks

# Jets

# Charged Particle Suppression

- Charged partons lose energy as they traverse the QGP via color interactions
- This results in reduced charged-particle yields in AA collisions as compared to pp
  - Strong  $p_T$  dependence
- Colorless probes can be used as reference

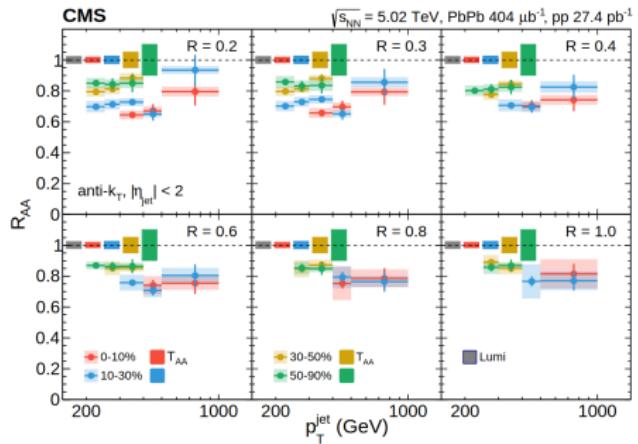

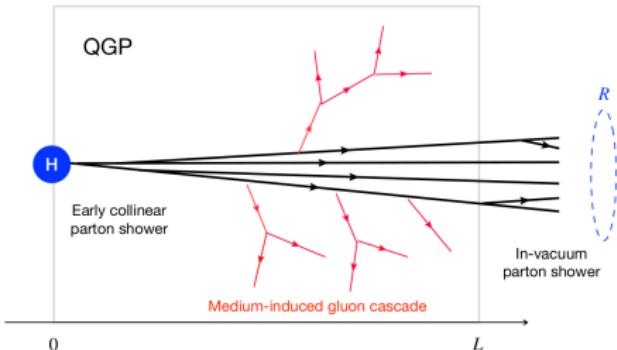

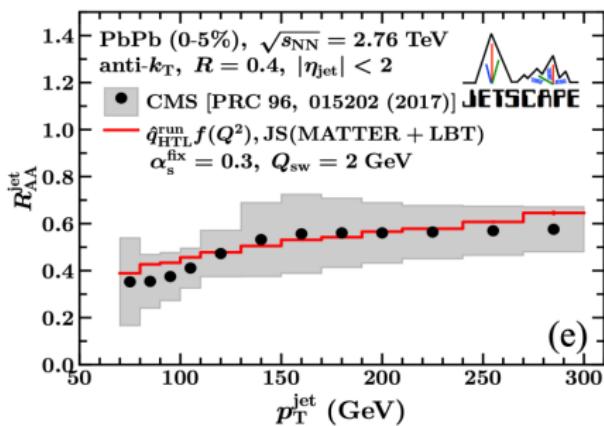

$$R_{AA}^{\text{ch}}(p_T) = \frac{dN_{\text{ch}}^{\text{AA}}/dp_T}{\langle N_{\text{coll}} \rangle dN_{\text{ch}}^{\text{pp}}/dp_T}$$

# Jet suppression

- Leading hadron measurements do not fully connect to the initial fragmenting parton
- Suppression of fully reconstructed jets is a better probe
  - Weak  $p_T$  dependence
  - Scales with centrality

$$R_{AA}^{\text{jet}}(p_T) = \frac{dN_{\text{jet}}^{\text{AA}}/dp_T}{\langle N_{\text{coll}} \rangle dN_{\text{jet}}^{\text{pp}}/dp_T}$$

# *b*-jet Identification

# Muon rel- $p_T$

## ***b*-jet measurements with CMS**

- Jets resulting from a framgenting *b*-quark are interesting objects because they are good tests many theories
  - Heavy flavor QCD
  - B-meson physics
- Many methods have been deployed to identify *b*-jets
  - Impact Parameter (IP) Significance
    - ▶ IP is the distance between the primary vertex and the point of closest approach of a track
    - ▶ *b*-jets tend to have wider IP distributions
  - Secondary Vertex Reconstruction
  - *b*-jets tend to have secondary vertices due to in-flight decays
  - Jet Probability
  - Soft Lepton Tagging
  - Deep Learning Techniques

# CMS Detector

## CMS DETECTOR

Total weight : 14,000 tonnes  
Overall diameter : 15.0 m  
Overall length : 28.7 m  
Magnetic field : 3.8 T

STEEL RETURN YOKE  
12,500 tonnes

SILICON TRACKERS  
Pixel ( $100 \times 150 \mu\text{m}$ )  $\sim 1\text{m}^2$   $\sim 66\text{M}$  channels  
Microstrips ( $80 \times 180 \mu\text{m}$ )  $\sim 200\text{m}^2$   $\sim 9.6\text{M}$  channels

arXiv:1706.04965

SUPERCONDUCTING SOLENOID  
Niobium titanium coil carrying  $\sim 18,000\text{A}$

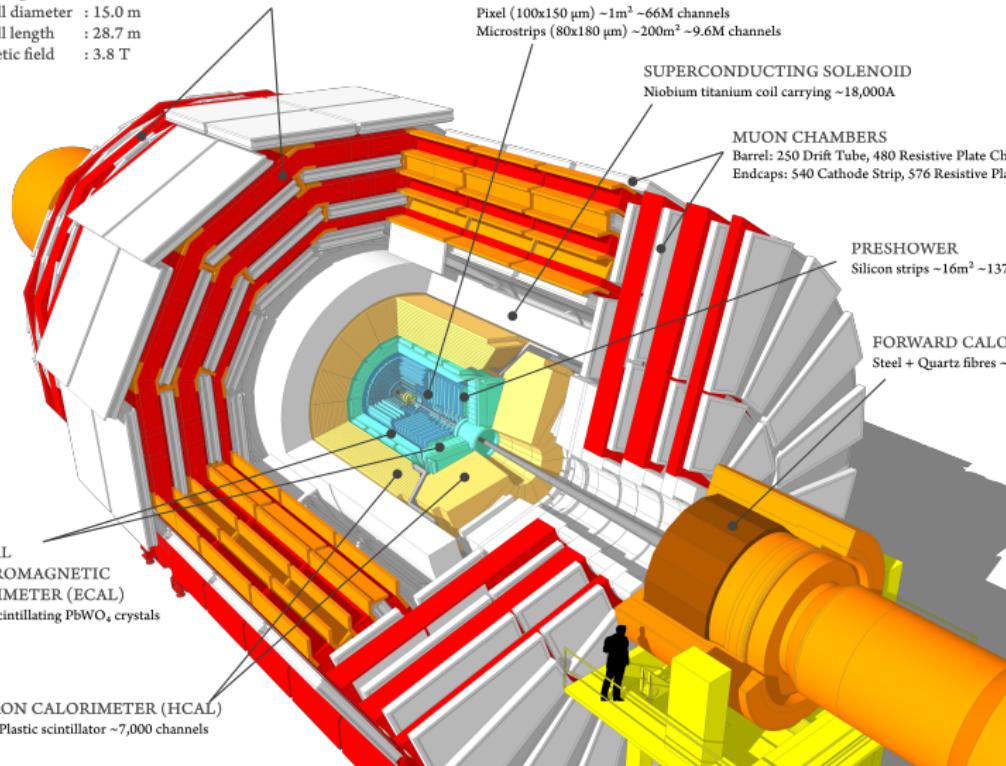

MUON CHAMBERS  
Barrel: 250 Drift Tube, 480 Resistive Plate Chambers  
Endcaps: 540 Cathode Strip, 576 Resistive Plate Chambers

PRESHOWER  
Silicon strips  $\sim 16\text{m}^2$   $\sim 137,000$  channels

FORWARD CALORIMETER  
Steel + Quartz fibres  $\sim 2,000$  Channels

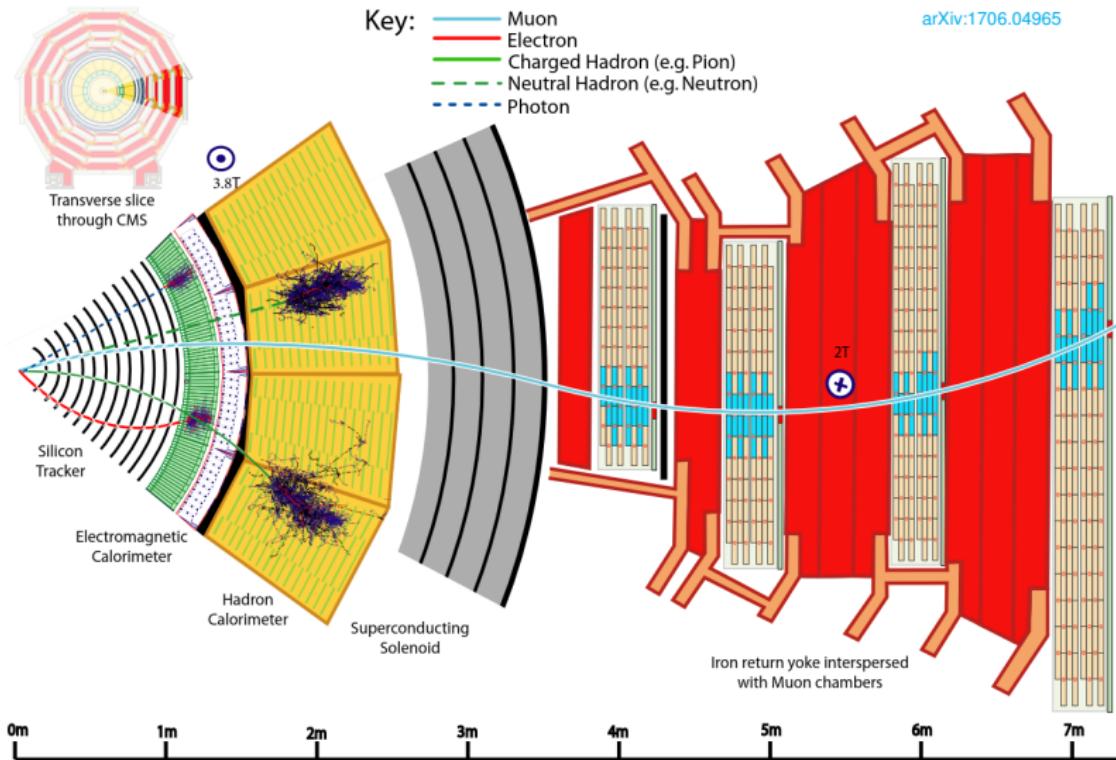

CRYSTAL  
ELECTROMAGNETIC  
CALORIMETER (ECAL)  
 $\sim 76,000$  scintillating  $\text{PbWO}_4$  crystals

HADRON CALORIMETER (HCAL)  
Brass + Plastic scintillator  $\sim 7,000$  channels
